PHASE I INSPECTION REPORT NATIONAL DAM SAFETY PROGRAM

APPROVED FOR PUBLIC RELEAS.

NEW YORK DISTRICT CORPS OF ENGINEERS

AUGUST 1981

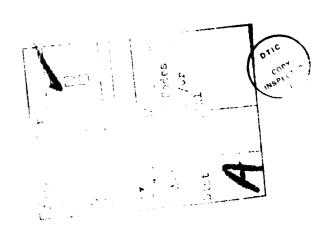

PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I Investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, and Spillway Test flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aide in determining the need for more detailed hudrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

PHASE I INSPECTION REPORT

NATIONAL DAM SAFETY PROGRAM

Name of Dam:

Mud Lock C & S Canal Dam

State Located:

New York

County:

Cayuga

Watershed:

Oswego River Basin

Stream:

Seneca River

Date of Inspection:

July 7, 1981

Assessment

Examination of available documents and a visual inspection of this dam did not reveal any conditions which constitute an immediate hazard to human life or property. However, several deficiencies were noted which should be evaluated and remedied.

The hydraulic/hydrologic analysis performed indicates that the spillway has sufficient capacity to discharge the peak outflow from one-half the Probable Maximum Flood (PMF), but not from the full PMF. However, overtopping is not likely to result in failure of the dam. In any case, spillway discharges occurring during large storm events will cause flooding in downstream areas along the canal, regardless of an overtopping failure. Therefore the spillway is assessed as inadequate according to Corps of Engineers guidelines.

The most serious deficiency is the deteriorated condition of the concrete on the retaining walls and on the spillway piers. Cracks, spalling and efflorescence throughout the structure indicate the need for more thorough maintenance work. Since the condition of the submerged section of the piers and spillway sill could not be evaluated, dewatering of the area, followed by a thorough inspection of both the concrete and steel work, is recommended. In lieu of dewatering the area, an underwater inspection of the steel and concrete may be conducted. The investigation should be commenced within six months of the date of notification of the Owner. Remedial measures deemed appropriate as a result of the investigation should be completed within 12 months.

Other deficiencies as outlined below should be corrected within 12 months of the date of notification of the Owner:

1. Cracks and spalling on the concrete retaining walls, piers, and counterweights should be repaired.

2. All steel work on the superstructure should be sandblasted, primed and repainted where necessary, to prevent continued rusting and pitting.

3. All accumulated debris should be removed from the vicinity of the taintor gates.

4. The end seals on the taintor gates should be replaced.

5. The area of minor erosion behind the upstream retaining wall on the right embankment should be backfilled and reseeded.

6. Trees and brush growing on the crest of the left embankment, and on the downstream toe of both embankments should be removed.

7. An emergency action plan should be developed for the notification and evacuation of downstream residents.

OVERVIEW
MUD LOCK C&S CANAL DAM
NY ID NO. 416

PHASE I INSPECTION REPORT NATIONAL DAM SAFETY PROGRAM MUD LOCK C&S CANAL DAM OSWEGO RIVER BASIN CAYUGA COUNTY, NEW YORK

SECTION 1: PROJECT INFORMATION

1.1 GENERAL

a. Authority

The Phase I inspection reported herein was authorized by the Department of the Army, New York District, Corps of Engineers, to fulfill the requirements of the National Dam Inspection Act, Public Law 92-367.

b. Purpose of Inspection
This inspection was conducted to evaluate the existing conditions of the dam, to identify deficiencies and hazardous conditions, to determine if these deficiencies constitute hazards to life and property, and to recommend remedial measures where required.

1.2 DESCRIPTION OF PROJECT

a. Description of Dam

The Mud Lock Dam at Cayuga Lake is one of the many water level control structures on the New York State Barge Canal System. The Cayuga and Seneca Canal flows eastward from Seneca to Cayuga Lake. From Cayuga Lake water flows over the spillway at Mud Lock Dam into the Seneca River, and northward to the Erie Canal. Navigation Lock No. 1, which is situated east of the east abutment of the dam permits passage of barge and recreational water traffic into the lower Canal. An inspection of the lock was not included in the dam inspection program.

The dam consists of a spillway with concrete side walls and six bays of taintor gates separated by concrete piers. Earthfill embankments to the right and left of the spillway section are protected by vertical concrete retaining walls on the upstream and downstream sides. Beyond the toe of the walls the the earth embankment slopes at 4:1 (H:V).

The retaining walls tie into the abutments of the spillway structure. The walls and piers are founded on piles driven to the top of bedrock. The combined length of the spillway and embankments is approximately 500 feet. The maximum height of the dam is 20 feet at the abutments, downstream of the sill. The minimum height is 17 feet at the retaining walls.

The spillway section has a total length of 220 feet, and the effective length of the combined bays is 180 feet. The crest of the spillway is a concrete sill 39 feet wide at elevation (El) 371.5 (Barge Canal Datum). According to available drawings, the sill is founded on wooden piles driven to varying depths, with sheet piling driven at the upstream and downstream ends of the sill. A timber crib was constructed

immediately downstream of the spillway to prevent scour in the discharge channel.

Flow over the spillway from Cayuga Lake is controlled by the taintor gates. The gates can be opened independently using rack and pinion mechanisms mounted on each pier. At the highest position, each gate creates an effective vertical opening of 15.5 feet, which is approximately three feet above the normal navigation elevation of the lake. Counterweights consisting of reinforced concrete blocks facilitates manual operation of the gates.

Access to the piers and handwheels is via a wood and steel walkway located upstream of the gates. The only access to the dam and spillway is a walkway along the top of the mitre gates at Lock No. 1.

There is no other outlet at the dam (other than the lock). The remains of an abandoned fish ladder can be seen adjacent to the left abutment of the dam, but the waterway has been blocked by dumped fill.

b. Location

The dam is located off Mud Lock Road, approximately two miles north of the Town of Cayuga, New York, and one mile south of the intersection of Route 20 and the Cayuga and Seneca Canal.

c. Size Classification

The dam is a maximum 20 feet high, but due to the large size of Cayuga Lake, has a maximum storage capacity of over 770,000 acre-feet. Therefore, the dam is in the "large" size category as defined by the "Recommended Guidelines for Safety Inspection of Dams".

d. Hazard Classification

The dam is classified as high hazard due to the presence of a number of homes downstream on the east side of the Canal.

e. Ownership

The dam is owned by the New York State Department of Transportation (DOT). Mr. William Schollenberger, of the Waterways Maintenance Division in Albany, was contacted concerning design and construction of the dam. Mr. Richard H. Aldrich of the Regional Waterways Office, Region 3, was contacted for information regarding operating procedures and maintenance of the dam. The Region 3 office is located at 333 East Washington Street, Syracuse, New York, 13404 (telephone 315/473-8194).

f. Purpose of the Dam

The dam is used primarily to regulate the water level in Cayuga Lake and the Cayuga and Seneca Canal for navigation purposes. In addition, its purpose is to, 1) provide additional lake storage to prevent flooding during periods of high runoff in the watershed, 2) maintain a stable recreation level in the lake, and 3) maintain a minimum flow in the Seneca River in response to local water quality requirements.

g. Design and Construction History The dam was constructed around 1912 for the New York State Department of Transportation, Canal Division, who also designed the structure. According to representatives of the DOT, there have been no major alterations to the structure since it was originally constructed. Shortly after construction a leakage problem was noted beneath the sill, and a section of wood and steel sheeting was driven upstream of the spillway as a cutoff. In 1973 the concrete sill at bay no. 1 (the east end of the spillway) was also regrouted through drill holes to prevent further seepage in this area.

*usable storage - does not include storage in Cayuga Lake below sill elevation

SECTION 2: ENGINEERING DATA

2.1 Geotechnical Data

<u>a. Geology</u>
Mud Lock Dam is located in the Finger Lakes Region, within the Ontario Lowland physiographic province of New York State. The province generally consists of a relatively low, flat-lying area which rises in elevation from Lake Ontario southeastward to the boundary with the Appalachian Uplands province. The Ontario Lowland is crossed by at least three major east-west trending escarpments formed by relatively resistant

major east-west trending escarpments formed by relatively resistant ridges of limestone and dolomite, which are in turn interbedded with less resistant shale units forming the lowland areas. Mud Lock Dam is located north of the escarpment formed by the Onondaga Limestone of Lower Devonian age. The area in the vicinity of the dam is underlain chiefly by Camillus shale of upper Silurian age.

Available publications do not indicate the presence of any faulting in the bedrock in the vicinity of the dam.

Depth to bedrock ranges from approximately 10 to 40 feet in the area of the navigation lock, based on available test borings. Overburden materials consist of gravel, sand, silt and clay that were deposited during and since the period of Pleistocene glaciation. The borings also show 4 to 6 feet of muck overlying the granular deposits.

b. Subsurface Investigations
Two drawings showing test borings and soil profiles along the Lock No. 1 canal were reviewed for this project.

2.2 DEJIAN RECORDS

Some design drawings dated 1910 and 1912 were available at the Department of Transportation office in Albany. Several plans showing details on the embankments, spillway, and taintor gates were reviewed, and the more pertinent drawings are included in Appendix E.

2.3 CONSTRUCTION RECORDS

No construction records concerning the original construction of the dam were located.

2.4 OPFRATION RECORDS

The dam is operated by personnel of the Department of Transportation, Waterways Division. The chief lock operator also regulates the position of the taintor gates as instructed by the DOT Region 3 office. Daily records of lake elevation and spillway discharge are kept by the operator and are available at the Regional office.

2.5 EVALUATION OF DATA

The data used for the preparation of this report was obtained from the New York State Department of Transportation. The available information appeared to be accurate.

SECTION 3: VISUAL INSPECTION

3.1 FINDINGS

a. General

Visual inspection of Mud Lock Dam was conducted on July 7, 1981. The weather was sunny with the temperature in the 80's. The water level at the time of the inspection was at El. 383.5, Barge Canal Datum, which is one-half foot below the top of the closed taintor gate.

b. Embankment

The grass cover on the right embankment was recently cut, which facilitated inspection of this side of the dam. The crest is relatively flat, with no apparent irregularities on the surface. Minor soil erosion due to runoff was noted behind the upstream retaining wall of the right abutment. Some vegetation is growing on the riprap slopes upstream and downstream of the retaining walls.

The left embankment is overgrown with brush, and the contact between the abutment and the abandoned fish ladder could not be distinguished. Gravel fill has been dumped into the fish ladder, which is now partially overgrown with vegetation. The only seepage noted on either the right or left embankment was through the fill in the fish ladder. Any seepage which may occur through the rest of the embankment would not be detected due to the tailwater.

The concrete side walls and the retaining walls, upstream and downstream, are in fair condition. Vertical construction and/or expansion joints have opened up at several places along the wall, particularly on the right embankment. Severe spalling is occurring in these areas, as well as along the upper edge of the upstream wall and along the entire surface of the downstream wall leading to the taintor gates. Heavy efflorescence was also noted on the walls.

c. Spillway

The spillway is in fair to poor condition, with the major deficiency being the deterioration of the concrete piers. Heavy spalling occurs on the tops of the piers, particularly toward the center of the spillway and at the gate bearing points. Efflorescence was noted through horizontal fractures in the sides of the piers, with minor amounts of vegetation growing in the cracks. The lower two-thirds of the piers, and the sill, could not be inspected due to the tailwater elevation. The submerged portion of the piers and sill was reportedly inspected in 1973 by towing a cofferdam barge upstream of the spillway and thereby cutting off the flow. Substantial leakage beneath the sill was reported in the 1973 Condition Report, which is included in Appendix E.

The rack and pinion mechanisms which operate the taintor gates appear to be in good condition, with only minor amounts of rust in some areas. Parts of the superstructure on the taintor gates have been recently painted, however, rust is visible in other areas of the beams. The steel plates on the downstream side were also rusted. The upstream side of the gates were submerged. All six counterweights on the taintor gates showed

heavy spalling on the lower corners. Five of the weights had horizontal fractures running along their entire length. In some places the fractures were as much as 3/4-inches wide.

At the time of the inspection, two of the six taintor gates were slightly open to permit a minimum flow of 200 cfs into the Seneca River. Heavy leakage was occurring around the end seals of three of the gates.

A significant accumulation of tree limbs and debris was noted on the upstream side of two of the gates. In addition, debris including several large tree trunks were caught in the lower part of the superstructure on the downstream side of the gates. Some of the debris appears to have been there long enough to sustain the growth of minor amounts of vegetation among the steel work.

d. Downstream Channel

The channel downstream of the spillway is wide and generally free from debris and overhanging trees. Part of the timber cribbing placed to prevent scour at the toe of the spillway was visible below the water surface, and appeared to be intact.

e. Reservoir Area

Cayuga Lake is approximately 35 miles long. However, due to the presence of a railroad causeway upstream of the dam, the fetch is only slightly more than one mile. There were no visible signs of instability or sedimentation problems on the perimeter within this immediate area, which consisted chiefly of low-lying vegetated marsh and woodland.

3.2 EVALUATION OF OBSERVATIONS

Visual inspection of this dam revealed the following deficiencies:

- 1. Heavy spalling, cracking, and efflorescence of the concrete on both the retaining walls on the embankment and the side walls, piers and counterweights on the spillway.
- 2. Rusted steel work on the taintor gates.
- 3. Heavy accumulation of debris both upstream of the gates, and lodged within the superstructure downstream of the plates.
- 4. Leakage around the side and bottom seals of the taintor gates.
- 5. Minor erosion of the soil on the earth embankment, behind the upstream retaining wall.
- 6. Minor growth of vegetation on the slopes beyond the retaining walls.

The reported periodic leakage under the sill could not be examined or evaluated.

SECTION 4: OPERATION AND MAINTENANCE PROCEDURES

4.1 PROCEDURES

Cayuga Lake is used for recreation and is part of the New York Barge Canal System controlled by the Department of Transportation. The flow of water out of the Lake and into the Seneca River is controlled by the taintor gates. The Region 3 office of the DOT gives daily instructions to the chief lock operator for operating the gates. A minimum flow of 200 cfs is maintained in the Seneca River at all times. Maximum elevation of the Lake for navigation purposes is 384.0, Barge Canal Datum at Mud Lock. Lake level is maintained within a range of 5 feet throughout the year, with the minimum level occurring during periods of high runoff in December, January and February. The purpose is to provide additional storage and thereby avoid flooding problems during the spring thaw.

4.2 MAINTENANCE OF DAM

The dam is maintained by the Department of Transportation. Grass mowing and other routine maintenance is performed by the lock operator and his staff as required. Biannual maintenance inspections are reportedly made by the regional maintenance crew. In addition, technical inspections of the structure have been made every two years since 1973 by DOT personnel. Copies of these inspection reports are included in Appendix E.

4.3 WARNING SYSTEM IF EFFECT

There is no warning system for notification and evacuation of downstream residents.

4.4 EVALUATION

The operation procedures on this structure are satisfactory. However, increased maintenance efforts are required to correct the deficiencies noted in Section 3.2.

SECTION 5: HYDRAULIC/HYDROLOGIC

5.1 DRAINAGE AREA CHARACTERISTICS

The drainage area to Mud Lock Dam is 1572 square miles (1,006,000 acres) as indicated on the map entitled "Oswego River Watershed" (Appendix F). The topography in the watershed changes from relatively flat and low-lying land in the northern part, to hilly terrain deeply incised by innumerable tributary streams in the southern portion. Elevations in the watershed range from 500 feet above mean sea level in the north, to over 1900 feet in the south.

This extensive watershed is generally comprised of rural, wooded and agricultural land. Areas of major development include the cities and towns of Geneva, Seneca Falls, and Ithaca.

The largest tributary into Cayuga Lake is Fall Creek, which flows westerly through Ithaca. In addition, Keuka and Seneca Lakes are hydraulically connected to Cayuga Lake by the Barge Canal System at the north end of the lake.

5.2 ANALYSIS CRITERIA

The large size of the watershed had to be considered in conducting the hydraulic analysis. For this reason the Probable Maximum Precipitation (PMP) was applied to three subareas of the watershed as follows:

1) rainfall directly on the lake surface, 2) runoff from the shorter tributary streams directly connected to the lake, and 3) runoff from the larger streams in the watershed, such as Fall Creek and the Cayuga-Seneca Canal. The three hydrographs were combined at the dam, and the total inflow was routed through Cayuga Lake in order to determine the peak discharge.

The hydraulic analysis assumes that for Keuka and Seneca Lakes the storage capacity in relation to watershed area is similar to that in Cayuga Lake. Therefore, the peak flow through the Cayuga-Seneca Canal into Cayuga Lake is insignificant when compared to the direct runoff into the lake. The results of the hydraulic analysis show that for runoff into Cayuga Lake an initial peak flow is a result of the rainfall directly on the lake. A second, higher peak occurs later when the runoff from the minor tributaries and remainder of the watershed reaches the dam.

The analysis of the spillway capacity of the dam and storage of the reservoir was performed using the Corp of Engineers HEC-1 computer model. The unit hydrograph was defined by the Snyder Synthetic Unit Hydrograph method, and the Modified Puls routing procedure was incorporated. The Probable Maximum Precipitation (PMP) was 19.0 inches (24 hrs., 200 sq. miles) from Hydrometeorological Report #33, in accordance with recommended guidelines of the Corps of Engineers. The floods selected for analysis were 50 and 100 percent of the Proabale Maximum Flood (PMF) flows. The PMF inflow of 3 5,360 cfs was routed through the reservoir and the peak outflow was determined to be 67,760 cfs. The one-half PMF inflow and routed outflow were 163,180 cfs and 30,850 cfs, respectively.

5.3 SPILLWAY CAPACITY

The spillway consists of a concrete sill with six bays of taintor gates separated by concrete piers. The effective length of the combined bays is 180 feet. The retaining walls on the embankment are at El 387.2, which is 15.7 feet above the elevation of the sill. With the taintor gates completely open, spillway capacity to the top of the wall is 34,392 cfs. This is assuming no tailwater effect caused by flooding streams downstream of the dam.

5.4 RESERVOIR CAPACITY

The normal water surface is maintained at a maximum elevation of 384 (Barge Canal Datum) for navigational purposes. Cayuga Lake has a surface area of 66 square miles, and a maximum depth of 431 feet. However, for the hydraulic analysis, only the usable storage, above the elevation of the spillway sill (371.5) was considered. The effective impounding capacity at El 384 is therefore 528,000 acre-feet. Surcharge storage capacity to the top of the retaining walls (El 387.2) adds 135,000 acre-feet, which is equivalent to a direct runoff depth of 0.1 inch over the entire watershed. The total calculated usable storage is 663,000 acre-feet.

5.5 FLOODS OF RECORD

The maximum known discharge at the site of the dam was 10,004 cfs on July 10, 1935. As a result of Hurricane Agnes in 1972, the water level in the lake reached El 387.5, with a discharge rate of 9422 cfs flowing through the spillway. The positions of the taintor gates during this flood period are unknown.

5.6 OVERTOPPING POTENTIAL

The analyses indicated that with the taintor gates open, the spillway has sufficient capacity to discharge the flow from a one-half PMF storm event, but not from the full PMF. The computed depth of overtopping for the full PMF storm is 3.9 feet over the retaining wall. All storm events exceeding 60 percent of the PMF will result in the dam being overtopped.

5.7 EVALUATION

The hydrologic/hydraulic analysis indicated that the spillway does not have sufficient capacity to discharge the peak outflow from the full PMF. During the peak flow, the earth embankments of the dam will be overtopped. Due to the presence of the concrete retaining walls on the embankments, failure of the dam as a result of overtopping is unlikely to occur. However, during large storm events, increased spillway discharge and overtopping will result in flooding along the downstream canal regardless of an overtopping failure. Therefore, the spillway is assessed as inadequate.

SECTION 6: STRUCTURAL STABILITY

6.1 EVALUATION OF STRUCTURAL STABILITY

a. Visual Observations

Visual inspection of the left (west) embankment and portions of the upstream slope of the right embankment was hindered by brush and trees growing in these areas. The crest of the right embankment was grass-covered and well maintained.

No areas of instability or active seepage were noted on the right embankment. Any seepage which may occur beneath the spillway could not be detected due to the tailwater. The crest of the left embankment was irregular, and covered with brush. The only seepage visible in this area was occurring through the fill that has been dumped into the abandoned fish ladder.

b. Design and Construction Data

Design drawings dated 1910 and 1912 are available from the DOT office in Albany. Pertinent drawings have been included in Appendix E. No other design data, specifications, or computations, and no construction records, were available.

c. Seismic Stability

The structure is located in seismic zone 2. No seismic stability analysis was performed.

SECTION 7: ASSESSMENT/RECOMMENDATIONS

7.1 ASSESSMENT

a. Safety

The Phase I inspection of Mud Lock Dam revealed the following conditions:

 Deterioration of the concrete on the side walls, piers and retaining walls of the spillway and embankments.

2. Rusting of the steel superstructure on the spillway.

3. Heavy accumulation of debris both upstream of the taintor gates, and within the superstructure.

4. Minor growth of vegetation of the crest of the left embankment, and at the downstream toe of both embankments.

The spillway capacity is inadequate for the peak outflow from the Probable Maximum Flood (full PMF). However, overtopping of the embankments is not likely to result in failure of the dam. In any case, spillway discharge during the peak flow will cause flooding in downstream areas regardless of an overtopping foilure. Therefore, the spillway is assessed as inadequate, but not spriously inadequate.

b. Adequacy of Information

The plans which were available for the preparation of this report were fairly complete and appeared to be accurate. However, no detailed post-construction information was available for the inspection. In additon, information of the design of the embankments and the nature of the fill was not available.

c. Need for Additional Investigations

It is recommended that a thorough examination be made of the submerged portions of the spillway to determine the condition of the concrete, particularly at the base of the piers, and the condition of the skin plates on the gates, and to evaluate any possible seepage which may still be occurring beneath the sill. The downstream areas of the embankment should by inspected after they are cleared of brush and trees.

d. Urgency

The investigation of the dewatered spillway section and embankment areas should be undertaken withing six months of the date of notification of the Owner. Remedial measures deemed appropriate as a result of the investigation should be complete with 12 months.

Other deficiencies as outlined below should be corrected within 12 months of the date of notification of the Owner.

7.2 RECOMMENDED MEASURES

a. Cracks and spalling on the visible portions of the concrete retaining walls, piers, and counterweights should also be repaired.

b. All steel work on the superstructure should be sandblasted, primed and repainted where necessary, to prevent continued rusting and pitting.

- c. All accumulated debris should be removed from the vicinity of the taintor gates.
- The end seals on the taintor gates should be replaced.
- The area of minor erosion behind the upstream retaining wall on
- the right abutment should be backfilled and reseeded.

 f. Trees and brush growing on the crest of the left embankment, and on the downstream toe of both embankments should be removed.
- g. An emergency action plan should be developed for the notification and evacuation of downstream residents.

DAM REPORT

July 3 (Date) 191 T

CONSERVATION COMMISSION,

DIVISION OF WATERS.

GENTLEMEN:

| I have the honor to make the following report in relation to the structure known as | |
|--|------------|
| the Mush Jock Foch I C&S Dam. | |
| This dam is situated upon the Lener (Give name of street) | |
| in the Town of Curelius County, | |
| about 9 Mill from the Village or City of Cara magnitude | |

December 3, 1915,

Hon. Frank M. Williams,

State Engineer,

Albany, W. Y.

Dear Sir: -

Receipt is acknowledged of your letter of November 29, 1915, enclosing sketch for the proposed fishway for dam #1 Cayuga-Seneca Canal.

We prefer a fishway with a slope of about one vertical to four horizontal and a width of four feet with compartments six feet long, the partitions to run obliquely; the top partition to have an opening 18 inches square and the bottom partition an opening 12 inches square and proportional in between.

We enclose herewith a pamphlet on Fishways for Dam, which we hope will be of use to you in this work.

Very truly yours,

GEO. D. PRATT, Commissioner,

By

Division Engineer.

McK/C.

Encl.

INSPECTION GUIDELINES

FOR

3C.000 TAINTOR GATES AND TAINTOR DAMS

The following guidelines are related to the Structure Condition Report for Taintor Gates and Dams (CAN 95) by the numbering system for the various elements.

The inspector should refer to Forms Instruction 900 CAN 95 before filling out the condition report.

3C.100 Stream Channel

- .101 Adequacy of Openings
 Adequacy may be determined by checking upstream high water level recordings during past years.
- .102 Freedom from Erosion & Scour

 Upstream and downstream should be scrutnized for any indication of deepening or widening of the lateral dimension of flow area. Check the graph of any bottom profile available from Regional surveys.
- .103 Freedom from Obstructions

 Debris or vegetation in the Waterways both upstream and downstream may reduce the width of the waterway, contributing to scour. Sand and gravel bars formed in the channel may increase stream velocity and lead to scour.
- .104 Bank Protection

 Examine the condition and adequacy of existing bank protection.

 Note whether channel changes are impairing or decreasing the effectiveness of present protection.

3C. 200 Substructure

- .201 Sills & Aprons
- .202 Piers Between Gates
- .203 Abutments
- ,204 Wing Walls

These elements containing concrete are susceptible to scaling, cracking, spalling, movement and rotation. Any of these conditions should be noted. Evidence of movement may be observed by noting any scoring of concrete by sides of gates or excessive wear on gate seal; and also by noting any displacement at joints in the concrete.

3C.300 Superstructure

- .301 Gate Skinplate
- .302 Side Seal Strips
- .303 Bottom Seal Strips
- .304 Main Structural Members
- .305 Cross Bracing
- .309 Railings

All steel elements should be inspected for rust, erosion, cracks, buckles, kinks, fine cracks at stress connections, steel incased in concrete for deterioration or movement at their common exposure and all rivets and bolts for tightness. Seal strips may have become worn to the degree that they no longer seal properly and need replacement.

.306 Counterweights

Determine if the counterweights are sound and properly affixed. Where steel members pass through or are embedded in the concrete check for corrosion of the steel member or rust stains on the concrete. Look for cracks and spalls. Determine if the gates are in balance.

.307 Bearings & Pins

Examine all bearings and pins for weakness, excessive play, corrosion, and undesirable deflection or bending.

.308 Needle Beam Catwalk

Statement .301 thru .305 referring to steel elements shall apply here. All wooden walkways should be inspected for signs of decay, weathering, and wear. The needlebeam should be positioned so that the operator's gears properly mesh with the rack.

.310 Paint

Examine all paint for cracking or chipping, scaling, rust, pimples, and chalking. If paint film has disentegrated, note if the prime coat or surface of metal is exposed. Note if spot or extensive painting is needed. Look for paint failure on horizontal surfaces or those which are most exposed to sunlight or moisture. Give particular attention to areas around rivets and bolts, the ends of beams, the seams of built-up members, the unwelded ends of stiffeners, and any other areas difficult to paint or that retain moisture.

3C.400 Machinery (Electrical)

.401 Motors

Determine if there is ample wear length on brushes, ventilating openings are unobstructed and any abnormal vibration. The commutator or slip rings should be clean. The motor should be properly lubricated and kept dry.

.402 Gears

The gears are to be properly lubricated, tight on shafts, no broken or cracked teeth, properly meshed and aligned, with no excessive wear.

- .403 Bearings
 Bearings shall be free of excessive play and properly lubricated.
- .404 Wiring
 Inspect any exposed wiring for signs of faulty, worn or damaged
 insulation. Also look for loose wires, poor wire splices, and
 inadequate securing of ground lines. Check inside of junction
 boxes for excessive moisture, drain hole, poor wire splices,
 and loose connections. Covers for junction outlets and switch
 boxes should be in place. Determine insulation resistance value.
- .405 Starters, Switches
 Check contacts of motor starters, limit switches and overtravel switches for pitting. Mechanical linkage should be clean, dry, and lubricated. Contactor coils are to be clean and leads secure.
- .406 Overload Protection

 Determine if the circuits contain the proper amperage circuit breakers and/or fuses.
- 3C.500 Operators
 - .501 Hand Wheel Bearings

 The bearings should be lubricated, and aligned so that the gears mesh properly. Any excessive wear should be noted.
 - .502 Hand Wheel Gears

 Gears should be checked for tightness and lubrication. Cracked or broken teeth shall be noted.
 - .503 Housing

 The housing assemblies should be free of any cracks or broken areas.
 - .504 Fasteners

 Operator housing assemblies shall be firmly and securely anchored in place. Check for loose or missing nuts, bolts, rivets, etc.
 - .505 Gear Covers

 Gear Covers should be in a position that will protect the gears

 from weather and to prevent the operator from entanglement while
 the machinery is in operation.

- .506 Locking Devices

 Locking Devices should be provided to prevent unauthorized use.
- 3C.600 Machinery (Lifting)
 - .601 Pinion Shaft
 The pinion shaft should be straight and true. The shaft should also be examined for excessive wear and proper lubrication at at the bearings. Inspect for excessive twisting of the shaft.
 - .602 Bearings
 The pinion shaft bearings shall be free of excessive wear and properly lubricated.
 - .603 Gears

 Check the alignment of all gears, locks, and interlocking devices.

 There should be adequate lubrication of all movable parts, particularly where meshing or contact occurs. All gears will be inspected for cracked teeth or hub. Keys are to fit tightly in keyways, holding gears firmly on shafts.
 - .604 Cable Drums

 Note if drums are tight on shaft and if the cables are properly aligned on drums. Excessive wear of drum groves should be noted.
 - .605 Rack Segments
 Inspect rack segments for excessive wear, broken or missing teeth, proper lubrication and alignment for mesh with the pinion gear.
 - .606 Lifting Cables
 Lifting cables should be inspected for wear damage, corrosion and inadequate lubrication. Cable connectors must be secure.
 - .607 Couplings
 Couplings shall be tight on shafts with all flange bolts in place and tight.
- 3C.700 Gate Bearing Points

Examine all bearings and pins for weakness, excessive play, corrosion, and undesirable deflection or bending.

Code 900 CAN 95

FORMS INSTRUCTION

Subj: Condition Report for

Taintor Gates and Taintor Dams

PURPOSE

For recording the results of field inspections of all taintor gates and taintor dams maintained by the Waterways Maintenance Subdivision. This form is also the source of input to the EDP program for listing the condition information.

PREPARATION

Completed in the field, in black ball point or black felt tipped pen, by the person performing the inspection. One form is used for each structure to be inspected.

- 1. The field inspector fills out the heading and enters the year and month when the inspection was performed in the boxes provided. Enter single digit months in the rightmost box.
- 2. Boxes 1 thru 7 Structure Identification Number. The field inspector enters the number for the taintor gate or taintor dam being inspected. The number is obtained from the EDP Listing of the Structure Inventory.
- 3. Boxes 8 thru 49 inclusive (except for boxes 28 and 29). The rating numbers to be inserted in these boxes by the field inspector are as follows:

9 - Excellent

7 - Good

5 - Fair

3 - Poor

1' - Poor minus

Criteria for applying these ratings to the various elements of the structure may be found in section 3C.000 of the Maintenance Quality Manual.

NOTE: There must be an entry in every box.

- a. If there is no such element on the structure enter N
- b. If the element is submerged or otherwise inaccessible enter X
- 4. Where the item to be rated covers more than one element on both the left and right (for example bank protection, piers between gates); enter an overall rating in the proper box and indicate any particularly bad conditions in the adjacent comments section.

PREPARATION - Cont'd.

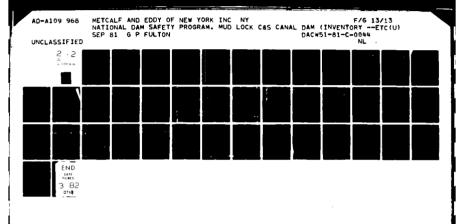

- 5. If the designation left or right is used under Comments, it must be in reference to the structure when facing downstream.
- 6. Box 50. The Regional Waterways Engineer only, enters one of the following rating numbers in this box:
 - 9 Good condition no repairs necessary.
 - 7 Preventive maintenance or minor repairs needed.
 - 5 Major repairs needed deferred scheduling.
 - 3 Major repairs needed schedule within one year.
 - 1 Immediate attention needed schedule as soon as possible.
- 7. The Regional Waterways Engineer will sign the completed form where indicated opposite box 50.

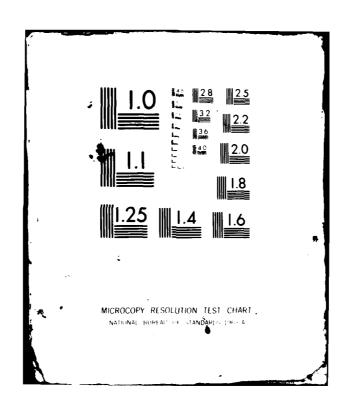

DISPOSITION

- 1. The Regional Waterways Engineer will have two copies made of the original report. He will then forward the original and one copy to the Waterways Maintenance Subdivision Main Office. The other copy will be retained in the Regional Waterways Office files.
- 2. The Waterways Maintenance Subdivision Main Office will review the form for completeness and reasonableness of entries. The original will be kept in that office and the copy will be forwarded to the Bureau of Data Services for processing into the data file.
